

A tropical beach scene with a clear blue sky, white clouds, a sailboat on the left, and three palm trees on the right.

Ubiquitous and Customized P2P Picture Sharing based on PIAX

Progress Presentation

(till Oct. 30th, 2008)

**Xiang Xiang (Visiting Researcher)
Graduate School of Engineering,
Osaka University, Japan**

Agenda

- **I. Overview of Functions**
- **II. Principle of P2P and PIAX**
- **III. System Design [Important]
[Agent and Peer Design]**
- **IV. Recommendation System**
- **V. Questions & Comments**

One can manage the pictures he/she has taken and the information in the P2P Internet will be updated synchronously.

Without Internet, the P2P network can be built based on wireless LAN.

Share ubiquitous pictures with others.

One can Use a PIAX Nano or a cell phone to take pictures with location information attached at any time and can optionally add comments to them.

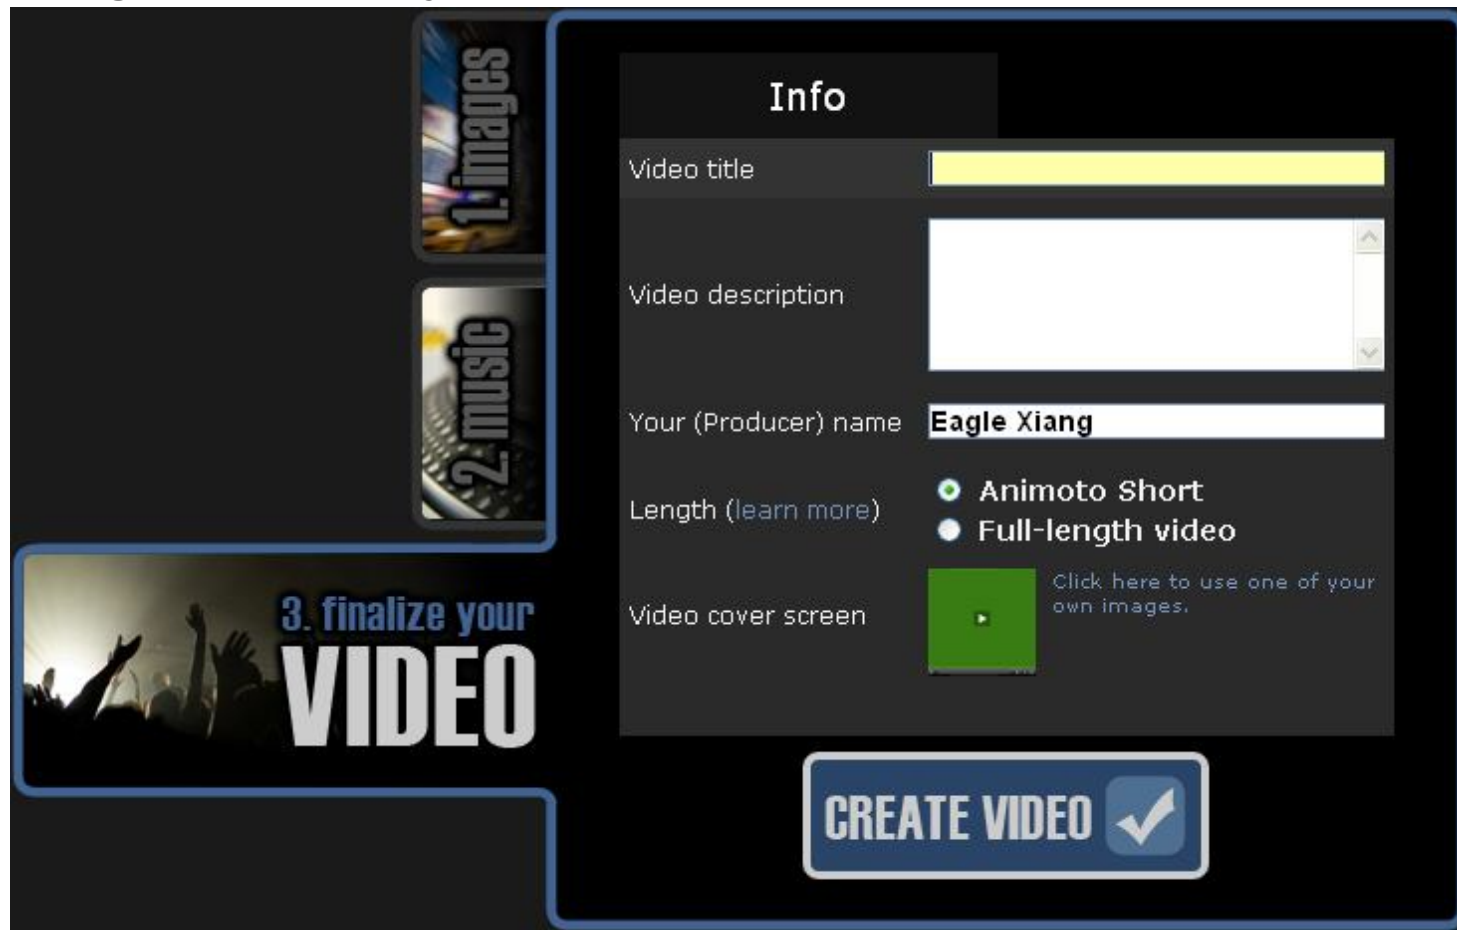

When a person is walking and there are pictures taken before at near locations, the application will notify him/her.

It may looks like: (from ANIMOTO)

Although for this project, how it looks like is not important

The screenshot shows the Animoto video creation interface. On the left, there are three steps: '1. images', '2. music', and '3. finalize your VIDEO'. The '3. finalize your VIDEO' step is highlighted. The main area is titled 'Info' and contains the following fields:

- Video title: A text input field.
- Video description: A text area with a scroll bar.
- Your (Producer) name: A text input field containing 'Eagle Xiang'.
- Length (learn more): Two radio buttons, 'Animoto Short' (selected) and 'Full-length video'.
- Video cover screen: A small video player thumbnail with a play button and a link 'Click here to use one of your own images.'

At the bottom right, there is a large blue button labeled 'CREATE VIDEO' with a checkmark icon.

Agenda

- **I. Overview of Functions**
- **II. Principle of P2P and PIAX**
- **III. System Design**
[Agent and Peer Design]
- **IV. Recommendation System**
- **V. Questions & Comments**

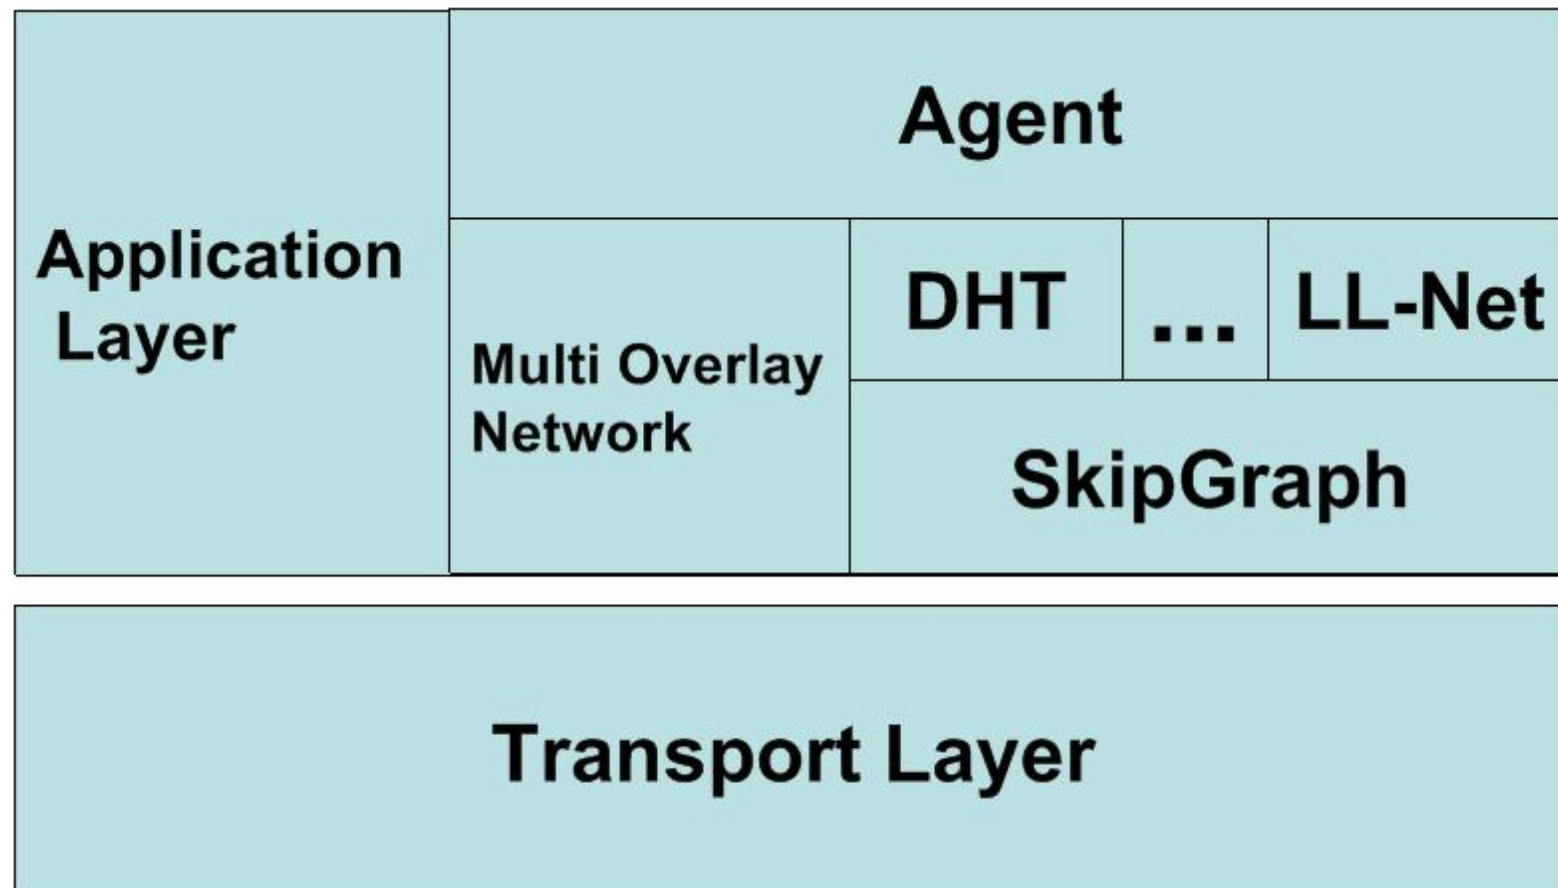

1. Overlay network (my understanding)

- built on top of another network
- nodes are connected by virtual or logical links

- Overlay network means that an application exists inside one layer(now I talk about Five Layer Architecture), especially the application network. Since the communication between a peer and another is based on the layers below, this kind of network is called "Overlay".

2. Multiple Overlay network

3. How do the DHT, LLNet, and ALM overlays use MSkipGraph?

- DHT and ALM search through SkipGraph according to Key, but LLNet does that according to peerId. The following is the data structure of a skip graph. The valid searching region is inside the dashed region.

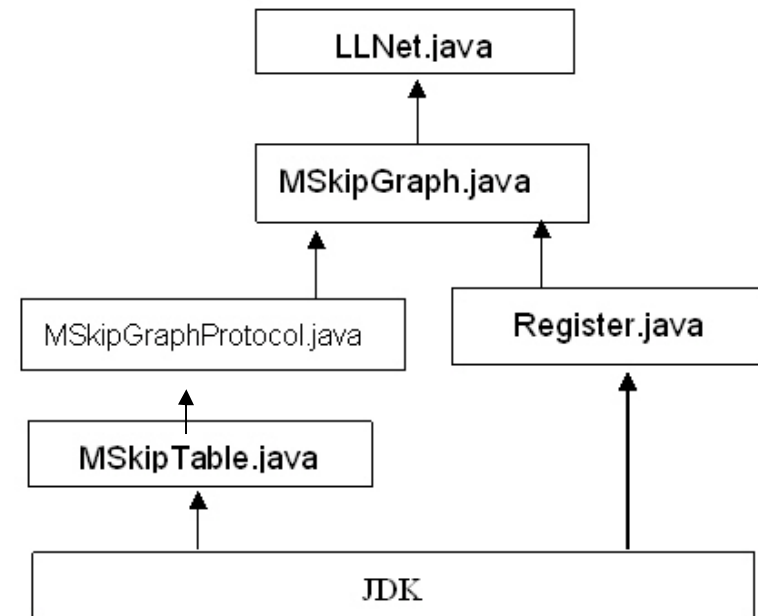

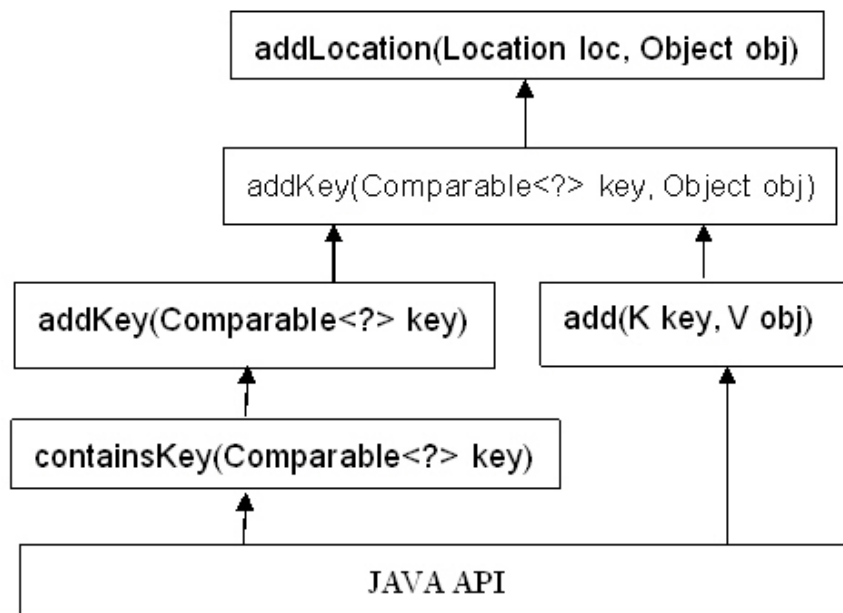

(1) In theory, for a DHT:

A skip graph with $n = 6$ nodes and $\lceil \log n \rceil = 3$ levels.

- (1) let's suppose that we want to search the peer with the key 75. We search from higher levels to lower levels, and from head (left) to tail (right). Hence, the key route of our searching will be: Head of Level 2 \rightarrow 33 in Level 2 \rightarrow 33 in Level 1 \rightarrow 48 in Level 1 \rightarrow 48 in Level 0 \rightarrow 75 in Level 0. Not until we find the Key 75, did we find the peer. Through that kind of searching, DHT uses the MSkipGraph. And in implementation, DHT implements MSkipGraphWrapper.

(2) In implementation, for a LL-Net:

4. How to describe a peer's position?

- we can use a key to describe the accurate position of one peer. It's because the key is the combination of (x,y) according to the **Z-sorting (Z-order)** rules. And (x,y) stands for the unique position of a peer in the 2-dimension map (longitude, latitude).

	x: 0 000	1 001	2 010	3 011	4 100	5 101	6 110	7 111
y: 0 000	000000 000001	000100 000101	010000 010001	010100 010101	100000 100001	100100 100101	110000 110001	110100 110101
1 001	000010 000011	000110 000111	010010 010011	010110 010111	100010 100011	100110 100111	110010 110011	110110 110111
2 010	001000 001001	001100 001101	011000 011001	011100 011101	101000 101001	101100 101101	111000 111001	111100 111101
3 011	001010 001011	001110 001111	011010 011011	011110 011111	101010 101011	101110 101111	111010 111011	111110 111111
4 100	100000 100001	100100 100101	110000 110001	110100 110101	000000 000001	000100 000101	010000 010001	010100 010101
5 101	100010 100011	100110 100111	110010 110011	110110 110111	000010 000011	000110 000111	010010 010011	010110 010111
6 110	101000 101001	101100 101101	111000 111001	111100 111101	001000 001001	001100 001101	011000 011001	011100 011101
7 111	101010 101011	101110 101111	111010 111011	111110 111111	001010 001011	001110 001111	011010 011011	011110 011111

5. PIAX principle (my understanding)

- The P2P network needs seeds to allow external peers to connect into the network. Seeds is not necessarily be fixed, and can be flexible.
- In PIAX, peers use peerID or peerName to communicate with other peers. Agents exist on peers. A peer can have many agents, and a agent can move from one peer to another peer. That kind of agent is called mobile agent; the agent which cannot move is called persistent agent.

- 
- We can use a Key to describe the unique position of a peer; and Key is stored in the multiple overlay networks, such as **DHT, LL-Net, ALM**. In fact, a peer(peer1) can have multiple positions, so it can have multiple keys. So then, if another peer(peer2) want to find peer1 by searching according to one key, then any key of peer1's multiple keys will be okay.
- 

6. PIAX Programming Guide

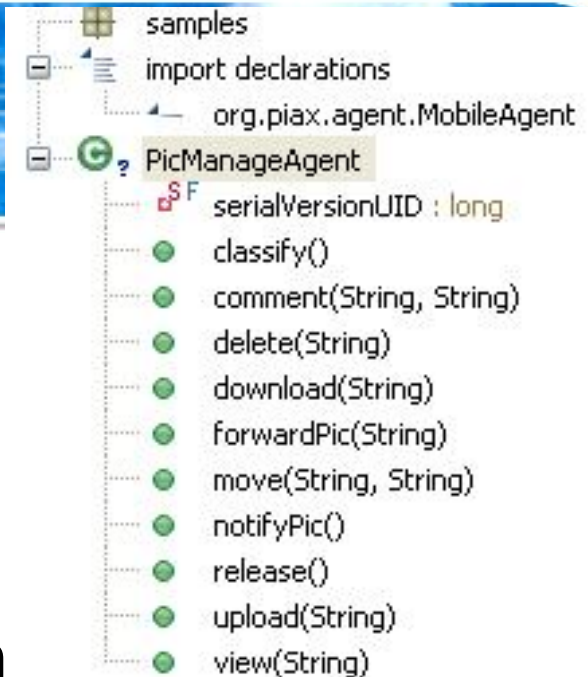

- In PIAX, when we want to make a peer to join the existed P2P network, we should call the method `join()`;
- If we want to change the position of this peer, we can call the method `move(double x, double y)`;
- If we want to start the peer with a specific position, we can directly call the method `join(double x, double y)`. In fact, that method is the combination of `join()` and `move(double x, double y)`.
- If we want to know the information of this peer, we can call the method `info()`. Then we'll know the `peerName`, `peerID`, `(host:port)`, `location`, `[key and objects]`.

- 
- Since Key can be accurate identity of a peer's position, then how can we know the value of a Key? In fact, we can use the method `get(String keyName)` and then it will return the value of that Key. Then how can we set a new Key or change the value of a Key? We can use the method `put(String keyName, String keyValue)`.
 - In order to communicate with other peers, only joining the P2P network is not enough. It also needs initialization. We can use `init()` to do that. In fact, `init()` calls the method `put(String keyName, String keyValue)` to set the `peerID` to be the value of its Key.
- 

- 
- If peer1 want to get to know another peer's (peer2's) information, it can call the method peek(String peer2_Name), as long as it knows the peerName of the peer2. The most important information peer1 will get is the peerID of peer2.
 - If we want to set a new agent for a peer, we just need to call the method mkagent(String agentClassName, String agentName). There're several kinds of agents defined, including MobileAgent, PersistentAgent. In reality, we can define agent (or called design agent Class) by ourselves, such as EchoAgent, HelloAgent, IshiAgt, SleepyAgent and TravelAgent in the packet samples.
 - After we set a new agent, we must want to check whether the agent has been added to the peer. In fact, we just need to call the method agents() for the peer, and then we can get a list of the agents existing on the peer.
 - and so on.
- 

Since I need to use the picture data with its location, I should use **LL-net.**

And the picture management class "PicManageAgent" should extend the class "Agent" and can have the methods showed in the right diagram:

- **First, what kind of query can applications or people will issue?**
 - a. **location-based search (pics taken in a specified region),**
 - b. **time-based search (pics taken during specified time period),**
 - c. **other attribute-based search (e.g, pics of person, animal pics, scenery pics, etc.)**
- **Then, give keys to pictures.**

Agenda

- **I. Overview of Functions**
- **II. Principle of P2P and PIAX**
- **III. System Design [Important]
[Agent and Peer Design]**
- **IV. Recommendation System**
- **V. Questions & Comments**

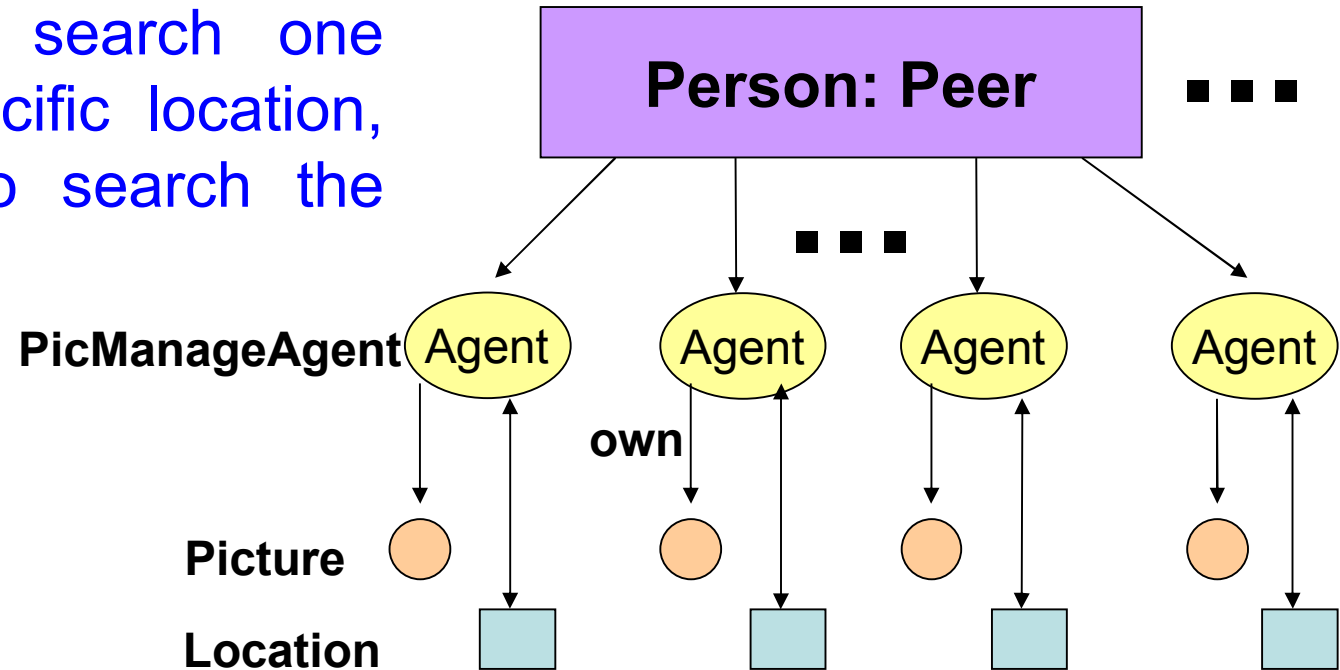

1. Application Scene of Peers (Location-based)

There are two ways to relate agents with locations. Here, one location can be understood as one geographical point (or called position). And it's supposed that one location just associates with one picture.

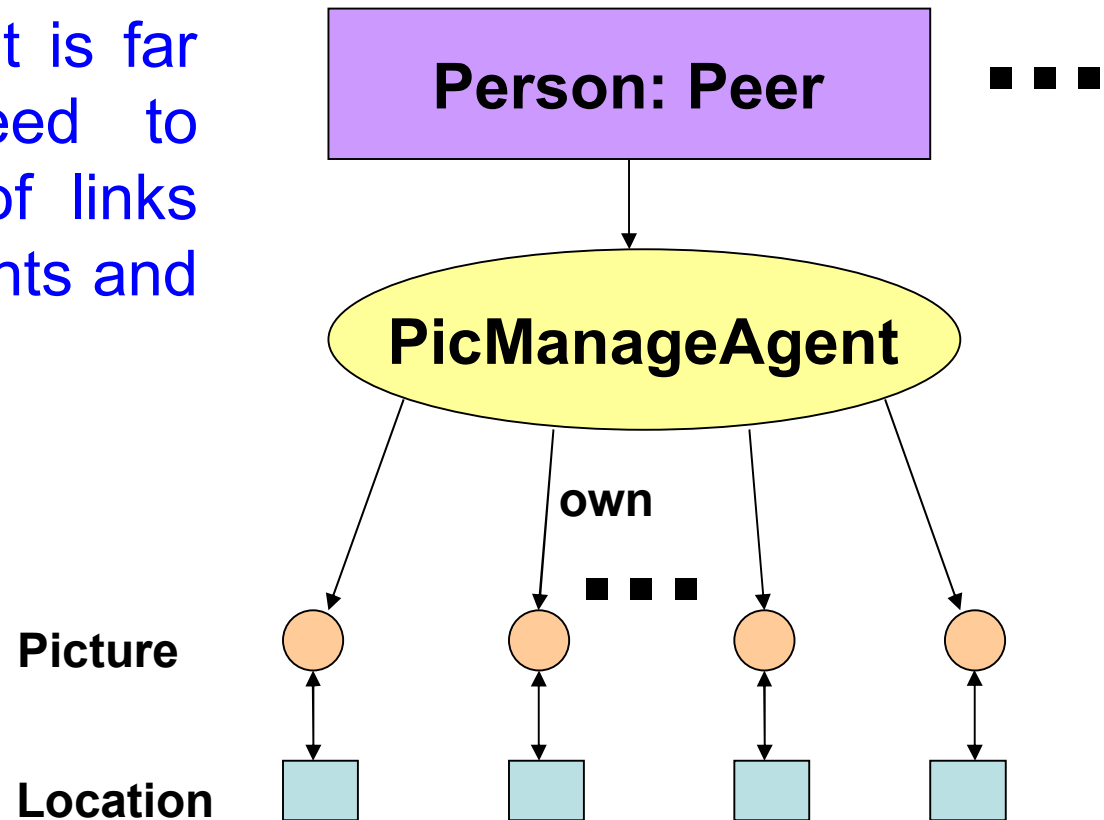

2. One Agent with One Picture

If we want to search one picture in a specific location, we just need to search the agent.

3. One Agent with Multiple Pictures

Just searching the agent is far from enough. We need to record the characters of links between PicManageAgents and pictures.

4. Pros and Cons of the Two Designs

	1 agent with 1 picture	1 agent with multi-pictures
Advantage	Easy to search pictures	Hard to search pics
Disadvantage	Larger memory space (more agents; high degree of agents, so too many links Between peers) <u>[When the data is large-scale, this advantage should be considered]</u>	Smaller memory space (just the opposite)

5. Pros and Cons of the Two Designs

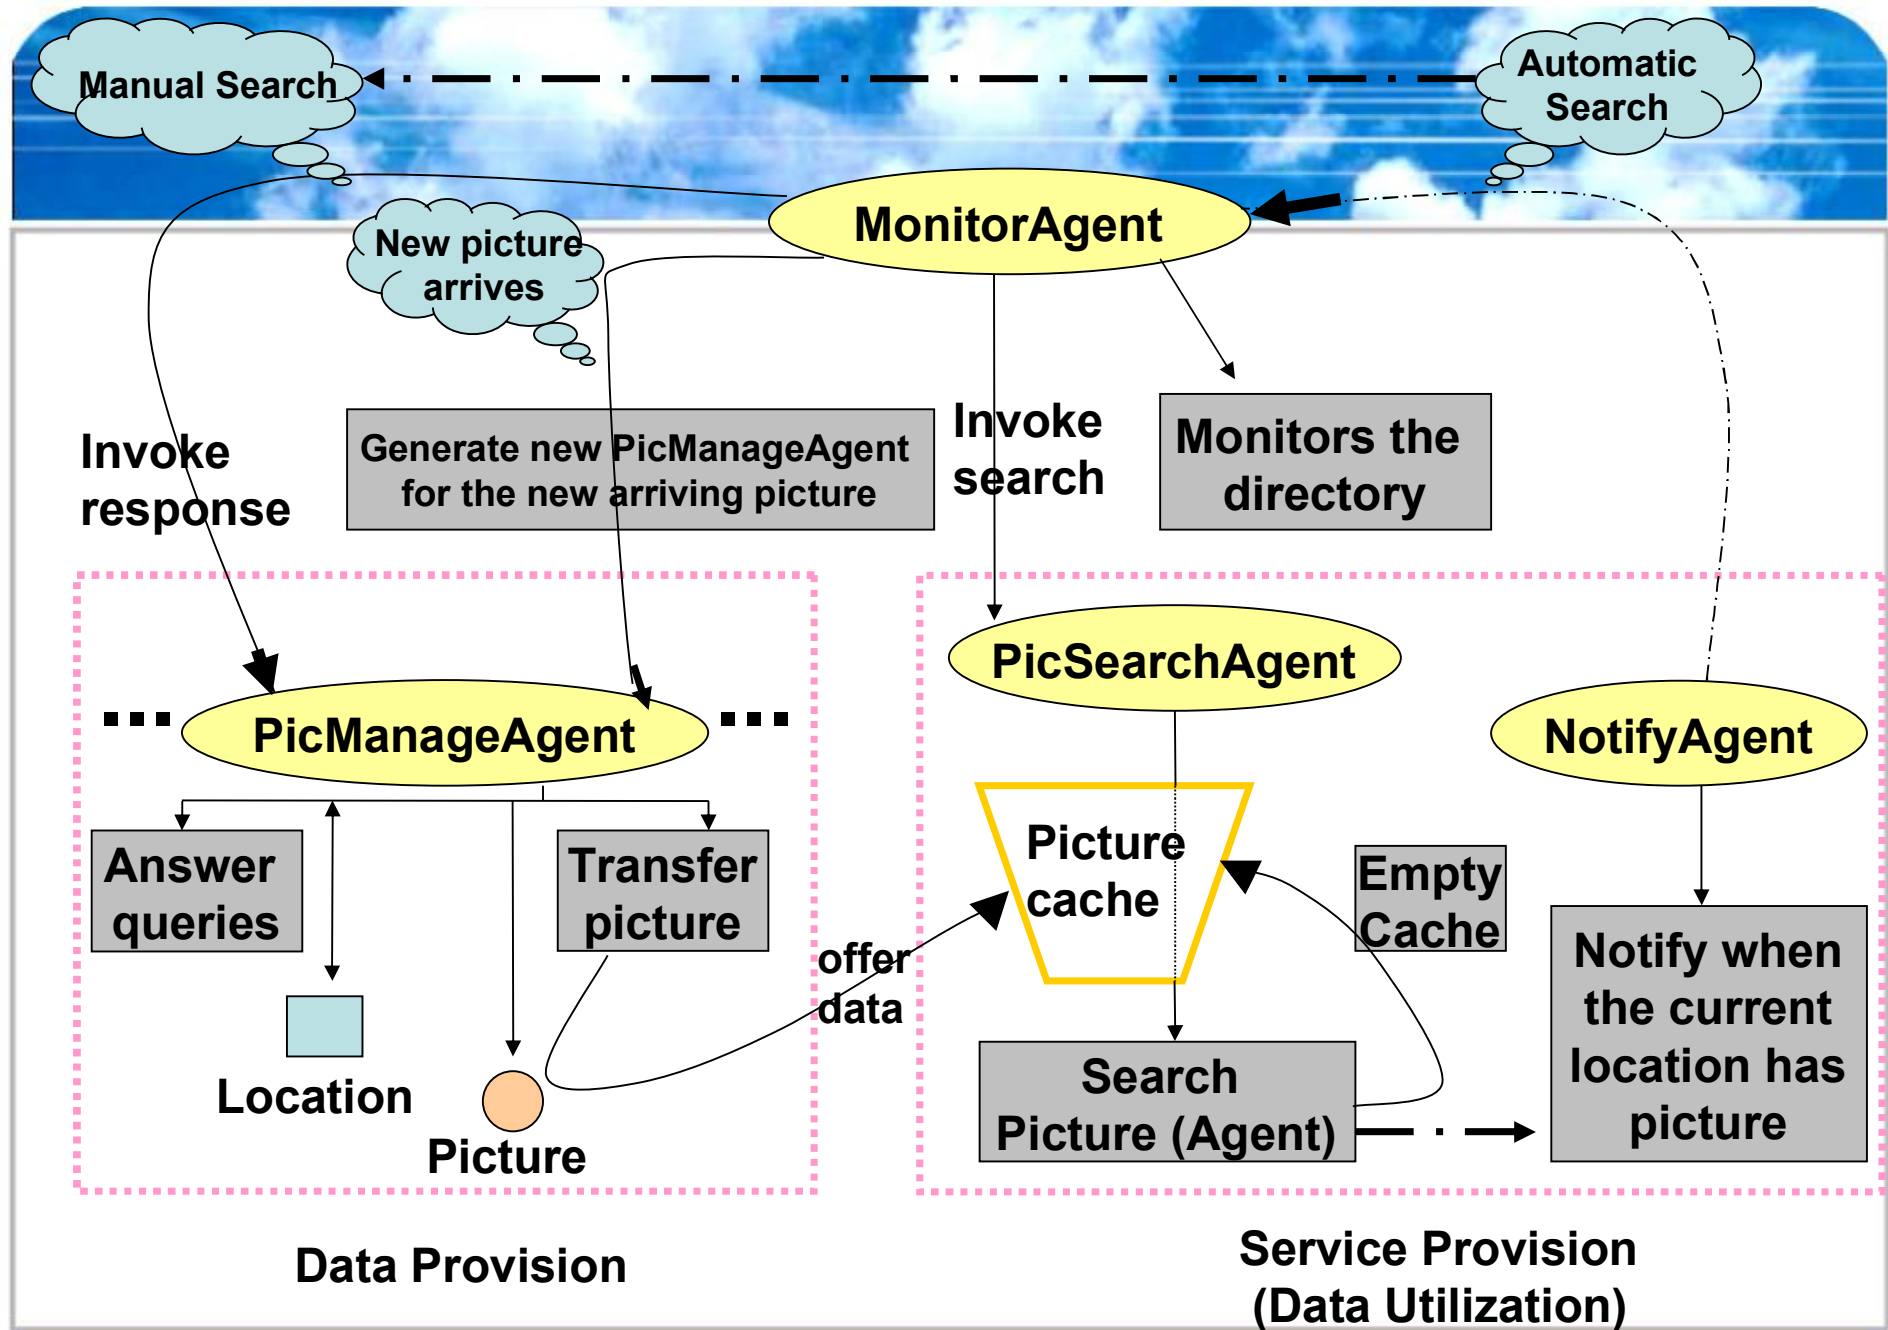

Links between peers

SkipGraph

In the perspective of Skip Graph, the query process requires to jump from one agent to another agent; thus, in the perspective of application layer, the query process requires to jump from one peer to another peer.

Then, in the 1 agent with 1 picture (location) design, one peer has many links with its agents. Now peer1 has 3 links with peer17. However, if one peer only has one agent (1 agents with multi-pictures), the links between peer1 and peer 17 **is 1 at the most**. Therefore, the 1 agent with 1 picture design will require larger memory space to store the agents and record the links.

6. Structure of the Peer

7. Process of Location-based Search (Z-Net, or called LL-Net in PIAX)

Suppose A receives a point query, whose destination is D.

8. Use PIAX API to Implement Location-based Search

Agent.java:

setAttrib(String name, Object value)

discoveryCall(...)

The screenshot displays the structure of the `PicManageAgent` class in a Java IDE. The class is part of the `PicShare` package and includes import declarations. The class contains several attributes, methods, and a constructor.

- Attributes:**
 - `loc : Location`
 - `myLocator : PeerLocator`
 - `peerName : String`
 - `piaxPeer : AgentPeer`
 - `renewRepo : boolean`
 - `seeds : Collection<PeerLocator>`
 - `serialVersionUID : long`
 - `agents : List<AgentId>`
 - `home : AgentHome`
 - `ragents : List<AgentId>`
 - `stime : long`
- Methods:**
 - `printUsage()`
 - `procArgs(String[])`
 - `classify()`
 - `comment(String, String)`
 - `delete(String)`
 - `discover(double, double, double, double, String, Object...)`
 - `download(String)`
 - `forwardPic(String)`
 - `getServiceName()`
 - `mainLoop()`
 - `move(String, String)`
 - `notifyPic()`
 - `printHelp()`
 - `release()`
 - `split(String)`
 - `upload(String)`
 - `view(String)`
- Constructor:**
 - `PicManageAgent()`

9. Work to do: Time-based and other attribute-based Search

- **III. System Design [Important]
[Agent and Peer Design]**
- **IV. Recommendation System**
- **V. Questions & Comments**

New Challenge: recommendation system of pictures

- Since one agent manages one position for a user in the "1 agent with 1 picture design", one user can have at most 1 picture in one location. But many people may pass by that location, so then that position can be related with many pictures. When a new user passes by that location, which picture is the best one to be recommended to that user?
- That's a complex question. One position can be related with many pictures, but those pictures can have different shooting time (day or night, different seasons, latest or old), can represent different topics (happy or sad, etc.; people, animal, object or sights). So we need a recommendation system to choose one picture from a lot of pictures to suit the user's interest. Such as, if the user often publishes (or called upload) pictures which are usually about sights, represent happiness, and are taken in the daytime. So the three characters can be used as constraints in query, then the query result will be fewer and more accurate, which will help the system to select one for the user. If after several selections, there are still several similar pictures, the system will choose one randomly. Of course, that is depended on how well the recommendation algorithm is. There are many kinds of recommendation (filtering) algorithms, such as Association Rules, Content Filtering, Collaborative Filtering and so on.
